Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These

numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information*

Security report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information*

Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the

same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These

numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give

much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These

numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP

technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions

best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of

a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These

numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP

technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the

same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and

only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.

Automating the protection of sensitive data is important because even people with the best of intentions make mistakes. The 2008 edition of CompTIA's *Trends in Information Security* report estimated that 30 percent of serious data breaches are caused by human errors, another 30 percent are caused by a hacker taking advantage of a human error, and only 40 percent are caused by a hacker actively overcoming flaws in technology. These numbers are quite a bit different than they were five years ago. The 2003 edition of the same report estimated that only 8 percent of serious data breaches did not involve some sort of human error.

People are getting better at protecting sensitive data, but they still not very good at it. It is still the case that most serious data breaches are caused by a failure of people instead of a failure of technology. Because of this, automating the process of protecting data will give much better results that just relying on error-prone people, and that is exactly where DLP technology promises to be able to make a difference.
